As the genetic material of the cell, DNA must perform **four important functions**:

It must be able to store all of an organism's genetic information.

It must be susceptible to mutation.

It must be precisely replicated in the cell division cycle.

A brief history of genetics.

3 potential outcomes of Heavy Nitrogen (^{15}N) experiments.

DNA Replication

DNA replication begins with separation of the two paired strands of double-stranded DNA by proteins that unwind the double helix, creating a replication fork.

Figure 12.10

Biology: How Life Works, Second Edition

© 2016 Macmillan Education

Replication can begin at any origin of replication. Eukaryotic chromosomes have many origins of replication, whereas prokaryotic chromosomes have one.

Each replication bubble has two replication forks that move in opposite directions.

Replication bubbles grow as replication continues.

At each replication fork, the new strand with the free 3' end is the leading strand and that with the free 5' end is the lagging strand.

When two replication bubbles meet, they fuse to make one larger bubble.

As the genetic material of the cell, DNA must perform **four important functions**:

It must be able to store all of an organism's genetic information.

It must be susceptible to mutation.

It must be precisely replicated in the cell division cycle.

At the molecular level

- **gene:** "a sequence of DNA that gives rise to a **functional gene product...**"
this product can (ultimately) be an RNA or a protein.

This is a little different from our first definition of a gene in **lecture 4**, when we defined it as

DNA

Nucleobases
of DNA

Ribose has a hydroxyl (-OH) group where deoxyribose has a hydrogen (-H).

Uracil has a hydrogen ($-H$) where thymine has a methyl ($-CH_3$) group.

RNA is usually **single-stranded**.

The sugar in RNA is **ribose**, not **deoxyribose**.

Wherever **thymine** is found in DNA, it is replaced by **uracil** in RNA.

RNA can fold over and base-pair with itself.

RNA comes in various forms/sequences, commensurate with function.

rRNA (81% by weight in *E. coli*; cellular RNA), which acts as nucleic acid scaffold for the ribosomes, which are the enzymes that copy the mRNA message into a polypeptide chain.

tRNA (15% by weight in *E. coli*; 60 different possible species), which is the link between the code of the **mRNA** and the **amino acids** of the **polypeptide**. The tRNA molecules specify the correct amino acid.

mRNA (4% by weight in *E. coli*; transient 0.5-10 minute to 24hr. life span), which is the transient information that is copied from the DNA.

RNA comes in various forms/sequences, commensurate with function.

rRNA (81% by weight in *E. coli*; cellular RNA), which acts as nucleic acid scaffold for the ribosomes, which are the enzymes that copy the mRNA message into a polypeptide chain.

3 Meanwhile, one of the strands joins a group of proteins, forming an **microRNA-protein complex**. The other strand, known as a **passenger strand** is usually discarded.

1 A protein called **exportin-5** transports a hairpin **primary microRNA (pri-miRNA)** out of the nucleus.

2 An enzyme called **dicer** trims the pri-microRNA and removes the hairpin loop, leaving a double-stranded microRNA duplex molecule.

4 In animal cells, the microRNA nucleotides typically don't pair up with the mRNA nucleotides perfectly. Their base pairing often follows a pattern though.

5 The micro RNA-protein complex's presence blocks translation as well as speeding up **deadenylation** (breakdown of the Poly-A tail), which causes the mRNA to be degraded sooner and translated less.

3 Meanwhile, one of the strands joins a group of proteins, forming an **microRNA-protein complex**. The other strand, known as a **passenger strand** is usually discarded.

AUG, which codes for the amino acid **methionine**, is called the **start codon**, which initiates the translational process.

Three of the possible codons are **STOP CODONS** (**UAA**, **UAG**, and **UGA**), which direct the ribosomes to STOP reading the mRNA; that is, they end translation.

First letter	U	<div>UUU</div> <div>UUC</div> <div>UUA</div> <div>UUG</div> <div>Phenyl-alanine</div> <div>Leucine</div>	<div>UCU</div> <div>UCC</div> <div>UCA</div> <div>UCG</div> <div>Serine</div>	<div>UAU</div> <div>UAC</div> <div>UAA</div> <div>UAG</div> <div>Tyrosine</div> <div>Stop codon</div> <div>Stop codon</div>	<div>UGU</div> <div>UGC</div> <div>UGA</div> <div>UGG</div> <div>Cysteine</div> <div>Stop codon</div> <div>Tryptophan</div>	U C A G
	C	<div>CUU</div> <div>CUC</div> <div>CUA</div> <div>CUG</div> <div>Leucine</div>	<div>CCU</div> <div>CCC</div> <div>CCA</div> <div>CCG</div> <div>Proline</div>	<div>CAU</div> <div>CAC</div> <div>CAA</div> <div>CAG</div> <div>Histidine</div> <div>Glutamine</div>	<div>CGU</div> <div>CGC</div> <div>CGA</div> <div>CGG</div> <div>Arginine</div>	U C A G
	A	<div>AUU</div> <div>AUC</div> <div>AUA</div> <div>AUG</div> <div>Isoleucine</div> <div>Methionine; start codon</div>	<div>ACU</div> <div>ACC</div> <div>ACA</div> <div>ACG</div> <div>Threonine</div>	<div>AAU</div> <div>AAC</div> <div>AAA</div> <div>AAG</div> <div>Asparagine</div> <div>Lysine</div>	<div>AGU</div> <div>AGC</div> <div>AGA</div> <div>AGG</div> <div>Serine</div> <div>Arginine</div>	U C A G
	G	<div>GUU</div> <div>GUC</div> <div>GUA</div> <div>GUG</div> <div>Valine</div>	<div>GCU</div> <div>GCC</div> <div>GCA</div> <div>GCG</div> <div>Alanine</div>	<div>GAU</div> <div>GAC</div> <div>GAA</div> <div>GAG</div> <div>Aspartic acid</div> <div>Glutamic acid</div>	<div>GGU</div> <div>GGC</div> <div>GGA</div> <div>GGG</div> <div>Glycine</div>	U C A G

The genetic code is **redundant** but not **ambiguous**. This means that many amino acids have more than **one codon**, but only one amino acid is specified for any one codon.

“Universal” Genetic Code
